## Abstract

### **Influences on smoking among Greek-Australians aged 50 and over: A mixed-methods study**

**INTRODUCTION:** Cigarette smokers have a higher probability of developing several chronic health disorders. Smokers of all ages can benefit by quitting, but many Australians continue to smoke. Older Greek-Australians have the highest prevalence of cigarette use in Australia. This study assesses smoking among Greek-Australians aged 50 and over and compares predictors of smoking behaviour in this group with the predictors for older Anglo-Australians.

**METHODS:** This investigation included three complementary studies: first, a systematic review of articles on smoking published between 1980 and 2011. The review focused on Randomized Controlled Trials (RCTs) and Quasi-RCTs in which the effects of specific behavioural interventions were examined. Papers were evaluated for inclusion and then data were extracted and interpreted. Second, snowball sampling techniques were used to identify 20 current smokers (12 males and 8 females) aged 50 or older. A qualitative study was designed to gather information on participants' perspectives and understandings regarding their reasons for smoking and their attitudes to quitting. Responses were collected via a semi-structured, face-to-face interview, conducted with the assistance of a Greek translator. The audio-taped interviews were translated and then their content was analysed. Third, a convenience sampling method was used to collect data for a cross-sectional survey of older smokers and non-smokers, including both Greek-Australians and Anglo-Australians in four subgroups: Greek-Australian Smokers (GSs), Greek-Australian non-smokers (GNSs), Anglo-Australian smokers (ASs), and Anglo-Australian non-smokers (ANSs). The data were collected over a six-month time frame from 27 October 2012 to 30 April 2013; subsequent analysis explored participants' knowledge of the health impacts of smoking and attitudes to smoking and/or quitting. Interview questions were designed to test possible differences in predictors of behaviour, knowledge, and attitudes between the four

subgroups. Overall, 387 people (106 ANSs, 82 ASs, 103 GNSs, and 96 GSs) participated in this study.

**RESULTS:** The systematic review identified some facilitators and predictors of effective smoking cessation programs targeting older smokers, and smokers with a non-English speaking background (NESB). The qualitative study results showed that older GSs had poorer knowledge about the negative health consequences of smoking as well as a more positive attitude to smoking consumption. They scored low for perceived benefits of smoking cessation and perceived risks of smoking use, while scoring high for perceived barriers to quitting. Few of the older Greek smokers expressed intention to quit, and their level of self-efficacy to embark on smoking cessation was low. Finally, comparing the results of the cross-sectional survey confirmed that GSs had poorer knowledge about the health consequences of smoking and had a more positive attitude to smoking. An integrated model (I-Model) was then developed based on four behavioural change models and theories, to illustrate the relationships of the research variables and to highlight smoking behavioural patterns among older Greek-Australians.

**CONCLUSION:** Older Greek-Australians have been identified as a priority group for smoking cessation interventions in Australia. The new proposed I-Model can be regarded as a comprehensive tool to help health care providers and researchers develop effective strategies to promote smoking cessation for older Greek-Australians.

## Acknowledgments

I would like to express my gratitude to my supervisor, Professor Paul Ward, and co-supervisors, Professor Carlene Wilson, Professor Julie Ratcliffe, and Dr. George Tsourtos for their support, valuable advice, guidance and encouragement throughout my PhD studies.

I also acknowledge the generous financial assistance of my scholarship sponsor; Ministry of Health of Islamic Republic of Iran.

My sincere thanks also go to Professor John Coveney from Flinders Prevention, Promotion, and Primary Health Care who donated \$5,000 for data collection and also to the faculty of Health Sciences, which sponsored my study with a grant of \$6,000.

I am deeply grateful to Luisa Stenta, Manager, Community Services of Greek Orthodox Community Services of SA Inc. who helped me in my project and provided me with many study facilities. I would also like to thank the managers of various recreational clubs, who allowed me to collect data, and also George Vlahos, who facilitated my access to the Glendi Greek Festival. My thanks also go to all participants in this study.

I would like to mention with appreciation all the lecturers (especially tutors in statistical analysis), staff and students in the Discipline of Public Health, Faculty of Health Sciences, Flinders University, who provided their advice so generously and supported me emotionally during the course of my study.

I would also like to thank the University of Rochester's Project 50+ researchers. They kindly allowed me to use some items from their questionnaire in constructing the final questionnaire for this project.

Finally, and most importantly, I wish to thank my family for all their constant love and encouragement — especially my mother, who prays for me all the time. And, of course, I owe heartfelt thanks to my beloved wife, Fatemeh, who has been with me for many years. Her unflinching support and encouragement was in the end what made this PhD possible.

## **Dedication**

This study is dedicated to my late father, and to my beloved daughter, Ava, who sustained me and motivated me when I encountered many difficulties along the way.

Figure 2: Process of selecting RCTs and QRCTs studies included in the systematic review .....	62
Figure 3: Distribution of Participants based on education level.....	154
Figure 4: Distribution of participants based on level of competence in English .....	155
Figure 5: Distribution of Greek participants based on preferred language.....	155
Figure 6: Distribution of participants based on employment status.....	156
Figure 7: Distribution of smoker participants based on the agreement of important people in their life to let them smoke.....	171
Figure 8: Distribution of participants based on sources of information.....	171
Figure 9: Comparison of estimated marginal means of smoking-related knowledge in different groups .....	174
Figure 10: Comparison of estimated marginal means of attitude to smoking.....	175
Figure 11: Compared estimated marginal means of anti-smoking sentiment.....	177
Figure 12: Compared estimated marginal means of ‘hard not to smoke’/‘hard to quit’ beliefs .....	178
Figure 13: Compared estimated marginal means of educationally ineffective believes .....	179
Figure 14: An Integrated Model of smoking cessation proposed for the study of Greek smokers ....	237

## **Glossary of terms**

**Attitude** “is defined as a function of beliefs. In other words, a person who believes that performing a particular behaviour will lead to positive outcomes will have a favourable attitude toward performing that behaviour” (Ajzen and Fishbein, 1980). In this study, ‘attitude’ refers to the participants’ attitude to smoking, that attitude being measured by a self-administrated questionnaire using a 14-point Likert scale.

**Knowledge** “refers to all that a person knows”(Chang, 2005). In the present study, it is defined as participants’ knowledge about smoking cessation benefits and smoking harms, and it was measured by a self-administrated questionnaire which included 15 true-or-false questions.

**Intention** “refers to a person’s perceived likelihood of performing a particular behaviour”(Ajzen and Fishbein, 1980). In the present study, ‘intention’ measures the smoker's likelihood of quitting in the next three months and was measured by one question which based on the Likert scale.

**Behaviour** “is defined as a series of actions” (Ajzen and Fishbein, 1980) and in this work it refers to smoking consumption. It was measured by a question about the number of cigarettes smoked during the preceding 24 hours.

As a minor determinant within social cognitive theory, **self-efficacy** describes an individual's confidence in their ability to coordinate and carry out the actions necessary to quit with perceived personal competence and overcoming perceived obstacles and costs (Bandura, 1998, Abraham et al., 2000). It was measured by a standard questionnaire which included a 9-point Likert scale.
