## SUMMARY

*Background* – Previous reports of abnormal auditory N2 and P3 event-related potentials (ERPs) suggest impaired discrimination, evaluation or context updating for infrequent target stimuli in post-traumatic stress disorder (PTSD). This study examines each of these processes by investigating high-resolution ERP topography during target detection for visual word stimuli.

*Method* – ERPs were recorded at 124 electrodes from 10 PTSD patients and 10 matched controls. Target detection tasks comprised blocks of equally probable red and blue words, with low probability target events. Detection of fixed target words in one color provided the basis for measurement of selective attention for color, stimulus evaluation and target detection processing. Alternative task instructions, with the same stimuli, required detection of any consecutive word repeats in an attended color, which demands working memory updating for non-target words. Comparison of attended non-target words from each task indicates the extra activity for updating working memory representations of target attributes. Thus, specific condition comparisons provide measures of stimulus discrimination and evaluation, working memory updating and target detection.

*Results* – PTSD patients had slower and less accurate motor responses in both tasks, with greater inaccuracy during the variable target task. There was abnormal ERP activity in PTSD at 200-300 ms in the left posterior temporal region during stimulus discrimination and target recognition. During evaluation of attended non-target words, PTSD patients demonstrate deficits in frontal and parietal regions at 400-500 ms. During working memory updating, at 400-600 ms, there was a delay in frontal activation, followed by smaller activity in parietal areas in PTSD. During target word recognition, PTSD patients demonstrate deficits in frontal activity, with greater occipital and parietal activity.

*Conclusions* – These findings indicate impaired evaluation and integration of new information in working memory. In particular, the results suggest failure in frontal executive systems, with greater dependence on visual processing for effective target detection. The current findings are consistent with neuropsychology studies that identify deficits of attention and memory for verbal information in PTSD. This study provides insight into the temporal components of attention and working memory in PTSD. It is proposed that working memory deficits arise from disruption to synchronized activity in distributed networks engaged in working memory processes.

## DECLARATION

I certify that this thesis does not incorporate without acknowledgement any material previously submitted for a degree or diploma in any university; and that to the best of my knowledge and belief it does not contain any material previously published or written by another person except where due reference is made in the text.

---

Darren Lee Weber

## ACKNOWLEDGMENTS

*All these intrusive recollections only have an experiential quality to them: when I have these flashbacks they are not explainable, I can't make things sequential. Up til now they had very little outline to them. Now a tiny fraction of these torture experiences have become knowable to me, but when I come closer to them and stop warding them off, I start having all sorts of problems of a different kind: I become confused, I lose things and start getting into accidents. The tragedy is the loneliness: the inability to convey the inner experience, and knowing that I cannot get out of it without going through it again.*

A PTSD patient; cited in van der Kolk, Burbridge & Suzuki, 1997, p. 99

*Humankind cannot bear very much lack of meaning. If we have to experience horror, there has to be a point. There has to be. In fact, it is not the horror itself that torments us so much as the need to understand. We have to get to the heart of the labyrinth where the minotaur lurks. We want to know that the labyrinth is mappable, that there is a minotaur, that there is at least something at the core of things which is responsible for all this dread, and we want to reassure ourselves that if we trail Ariadne's thread behind us we can find a way out again.*

Janette Turner Hospital, *The Last Magician*, University of Queensland Press, 1995

This work is dedicated to the trauma victims, especially those who freely assisted this research. I hope that we can illuminate Ariadne's thread and the way out.

I am indebted to my supervisor, Dr. Richard Clark, for his faith in my capacities and the opportunities to work on exciting projects. Being enthusiastic and determined, yet not always dedicated to one purpose, the supervision was not always easy, but you provided a good balance of encouragement, persuasion and discipline. I've grown to understand, respect and value your guidance and the opportunities you generate, while I've also grown more confident in my own judgment. You've supported me well; I hope the work lives up to all your expectations.

Prof. Alexander McFarlane is the inspiration of this work. Along with Prof. Phillip Morris, Prof. McFarlane was responsible for patient diagnosis and referral for this study. I would also like to extend my gratitude for his comments on this publication. I hope this work provides some of the answers we are all seeking.

Many students have been there with me, among them Diane Pomeroy, Geoff Fraser, Kathryn Moores, Sean Fitzgibbon, Brett Pearce, and Stan Orr; I want to thank you all for helpful discussions. I also thank you for your friendship. We've all strived to attain the best we can, nobody can ask more than that.

I would also like to thank all the people who helped me with the work. To work with high-density electrophysiology requires technical skill and assistance. Leon Snigg and Paul Douglas, our biomedical engineers, not only support our work, but also teach many valuable lessons. Neuroscan technicians (especially Pete Delgado) and all the people on their email list have given valuable advice. I would like to thank various computer systems officers over the years, but mostly James Tizard, for being the first computer guru in my life. I'm also indebted to valuable guidance on mathematical physics, especially the surface Laplacian, from Dr. Jim Bashford, Dr. Mike Teubner, and Dr. Tom Ferree. Dr. Robert Oostenveld helped with surface interpolation and contour mapping in matlab, which resulted in the realistic scalp topographic maps in this work. Finally, Dr. Gregory Simpson was very kind to support me during the final stages of writing.

Dr. Natalie Skinner (Dr. Nat!) has been there to show me the way and encourage me to rise to the challenge. You've given me support beyond measure. The wings were there, but you gave me the air. You're always in my heart, I'm forever grateful for your love.

Last, but not least, my family has supported me more than I can say. They've given me confidence in my abilities, encouraged an enquiring mind, and provided a loving stable home. When I wanted to go to university, they suggested that a trade or accounting job would secure my welfare. However, I was fascinated with academia, craving for knowledge and guidance on how to think (perhaps without enough consideration for welfare). The university opened my mind to a world of possibilities. I should thank the Whitlam federal labor government for opening university education to those with ability, not just finance, during the 1970s. In this regard, I respect and value the ethical foundations of Flinders University, especially equality of opportunity, and I hope those values survive difficult economic and political pressures. Anyhow, I guess I still live on a precarious basis, surviving on research grants is inherently risky, but the work has sustained me somehow. In the lean times, my family was there to support me. I hope you trust me now to make it all work and to find my own way. I hope all this study and now this PhD is a step in the right direction.
